

OMI Symbolic Grammar

Omicron Defines the Unit Outside the Units

One of the primary goals of OMI is to avoid the ambiguity of ordinary computing vocabulary.

Words such as:

- object
- node
- record
- frame
- receipt
- document
- message

already have multiple meanings across programming languages, databases, operating systems, networking, distributed systems, and mathematics.

Rather than redefining those words, OMI introduces a symbolic grammar.

The `Omi-` prefix declares that the word belongs to the OMI protocol itself.

It is therefore interpreted according to OMI's constitutional rules rather than conventional computer science terminology.

This is analogous to how the mathematical symbol $\emptyset$ immediately identifies the empty set instead of the English word "nothing."

The purpose of Omicron is therefore not merely to name an object.

It defines a symbolic unit outside ordinary units so that the protocol cannot accidentally inherit conflicting meanings.

Canonical OMI Symbolic Grammar

The protocol is organized as a deterministic sequence of symbolic transformations.

Omi-Attribution

↓

Omi-Projection

Every stage has exactly one responsibility.

Omi-Notation

The symbolic representation of a relation.

An Omi-Notation is syntax.

It is neither accepted nor rejected.

It simply declares structure.

Examples include:

- `omi---imo`
- `o---o`
- `/---/`
- `?---?`
- `@---@`

An Omi-Notation is the symbolic grammar of the protocol.

Omi-Citation

An addressed Omi-Notation.

A citation binds notation to deterministic scope.

Examples:

```
omi:FF/fs/gs/rs/us#relation
```

or

```
o---o/---/?---?@---@
```

A citation is addressable.

It is not yet validated.

Omi-Delta

The canonical transformation primitive.

Omi-Delta represents deterministic change.

It is named in honor of the Atomic Kernel Delta Law.

Canonical doctrine:

XOR witnesses difference.

Rotation preserves orbit.

Unary composition constructs behavior.

Shift only stages the next frame.

Validation determines state.

Omi-Delta is therefore not merely an arithmetic operation.

It is the constitutional notion of lawful transformation.

Every deterministic rewrite in OMI is an Omi-Delta.

Examples include:

- Delta Law
- Karnaugh reduction
- Boolean minimization
- combinator construction
- unary composition
- routing normalization
- address normalization

Difference is witnessed.

Structure is preserved.

Omi-Attestation

Validation produces an attestation.

An attestation does not replace the notation.

It describes the verified state of the notation.

Examples:

```
candidate  
validated  
accepted  
rejected  
deprecated  
merged
```

An attestation belongs to a citation.

It is not the citation itself.

Omi-Attribution

Once attested, a notation may be attributed into larger structures.

Examples include:

- constitutional grid
- JSON Canvas
- Markdown
- Blackboard
- hardware topology
- distributed routing
- version history

Attribution binds meaning to context.

It does not alter identity.

Omi-Projection

Projection realizes an attributed notation on a particular carrier.

Examples include:

- Markdown
- JSON Canvas
- SVG
- DOM
- React
- OpenGL
- LoRa
- GPIO
- firmware
- eMMC
- bitboards

Projection is always downstream.

Projection never determines authority.

Omi-State

State describes the current deterministic condition of an OMI relation.

Examples:

```
candidate  
  
validated  
  
accepted  
  
rejected  
  
deprecated  
  
merged
```

State is metadata describing a notation.

It is not the notation itself.

Omi-Phase

Phase describes where a notation currently resides within the constitutional pipeline.

Examples:

Declaration

Truth Gate

Decision Table

Karnaugh

Combinator

Delta

Validation

Projection

A phase is temporal only within the logical pipeline.

It is not physical time.

Omi-Transform

A deterministic mapping between phases.

Examples:

- normalization
- reduction
- encoding
- decoding
- routing
- projection

Every transform must preserve constitutional invariants.

Omi-Loop

A deterministic recurrence.

Examples include:

- Tetragrammatron orbit
- Metatron observation cycle
- circular slide rule
- unary composition
- Polybius traversal

An Omi-Loop is not an imperative loop.

It is a lawful recurrence over notation.

Omi-Psi

The observation surface.

Omi-Psi represents interpretation without changing authority.

Examples include:

- observers
- views
- inspections
- Blackboard visualization
- Canvas rendering

Observation never changes the notation.

It only changes the current view.

Constitutional Principle

The symbolic grammar deliberately separates identity from behavior.

Omi-Notation declares.

Omi-Citation addresses.

Omi-Delta transforms.

Validation determines.

Omi-Attestation witnesses.

Omi-Attribution contextualizes.

Omi-Projection realizes.

Omi-Psi observes.

No stage may assume the responsibility of another.

This separation allows every carrier, runtime, document, hardware target, and projection surface to share the same deterministic symbolic grammar while remaining independent implementations.
